

# A NOVEL HEPATITIS B VIRUS

Inventor: Jian Zheng

[illegible]

## BACKGROUND OF THE INVENTION

Hepatitis B virus (HBV), a small double stranded DNA  
5 virus, can cause a wide spectrum of clinical  
presentations: asymptomatic carrier state, acute self-  
limited hepatitis, fulminant hepatitis, and chronic  
liver diseases including chronic hepatitis, liver  
cirrhosis, and hepatocellular carcinoma. It has a  
10 circular genome of 3182 to 3221 base pairs (bp). Four  
major subtypes have been identified and can be  
differentiated by antibodies that recognize the  
different epitopes on the HBV surface. The HBsAg  
particles carry the common determinant, "a", as well as  
15 d or y and w or r subtype determinants, and are  
classified into the four major subtypes, i.e., adw, adr,  
ayw and ayr. Rare sera contain HBsAg particles with all  
four-subtype determinants (adywr). The antigenic  
determinants for the main HBV subtypes: adw, adr, ayw  
20 and ayr lie in the surface or "S" polypeptide. Two  
amino acid residues in particular, encoded by the S gene  
at codon positions 122 and 160, have been postulated to  
determine the different antigenic subtypes. While, the  
preC regions have frequently been reported to have  
25 mutations rendering HBe Ag negative. The virus has a  
high rate of mutation relative to other DNA viruses due  
to its mode of replication by reverse transcriptase of  
its pregenomic RNA. The importance of a novel mutant

can be reflected in vaccine escape and HBsAg detection failure, implicating a public health problem.

#### **Summary of the Invention**

5 We have identified and characterized a new surface  
mutant of HBV. The mutant was isolated from a  
symptomatic patient with Down's syndrome who was found  
to be persistently positive for both for HBsAg and anti-  
HBs Antibody (Ab) with an equally long-lasting anti-HB  
core (c) IgM Ab. With a panel of six monoclonal  
10 antibodies (mAb(s)) to HBsAg, we evaluated the mutation  
influence on the major epitope of the "a" determinant  
antigenicity.

#### **Brief Description of the Drawings**

15 Figure 1 illustrates the phylogeny tree of the HBsAg  
genomes and the accession numbers. Sequence of S1 -  
S13 strains are obtained from reference (Norder H,  
Hammas B, Lofdahl S, Courouce AM, Magnus LO.  
Comparison of the amino acid sequences of nine different  
20 serotypes of hepatitis B surface antigen and genomic  
classification of the corresponding hepatitis B virus  
strains. J Gen Virol. 1992 May;73 ( Pt 5):1201-8);  
GenBank accession numbers are given for the rest of  
strains.

#### **Detailed Description**

A sample was taken from a 43-year-old white male patient  
with Down's syndrome who presented with jaundice to the

American University of Beirut Medical Center in March 1999. The patient had no history of immunization to HBV, no transmissible risk factor including blood transfusion, IV drugs, homosexuality, family HBV infection or hemodialysis. During investigation, he was found to have elevated liver function tests (LFT): ALT 450 IU/L (range 10-35 IU/L), AST 250 IU/L (range 10-40 IU/L), gamma-GT 383 IU/L (range 10-50 IU/L), Bilirubin was 3.8/2.6 mg/dL (total/direct) (range, total: 0.1-1.2 IU/L and direct: 0.0-0.2 IU/L). More significantly, we noted incongruity in the HBV blood tests. The HBV markers test results using enzyme immunoassay (EIA) methodology were as follows: HBs Ag positive ( $>2/0.051$ ), anti-HBs Ab positive (0.417/0.206), anti-HBc IgM Ab low positive (0.371/0.208), anti-HBc IgG Ab strong positive ( $>2/0.412$ ), HBe Ag negative and anti-HBe Ab positive (0.197/0.830, a competitive assay). Both the anti-hepatitis A Ab and the anti-hepatitis C Ab were negative. Due to the discrepancy in the HBV markers, molecular methods were used to confirm the HBV antigen.

The patient was continuously followed up for LFT that decreased consistently over the following ten months including AST 80 IU/L. However, the HBV markers that were repeated ten months after initial presentation revealed both HBsAg positive ( $>2/0,056$ ) (DiaSorin, Italy) and anti HBs Ab positive (56/5) (BioMerieux, Mini-Vidas, France), and the persistence of a low

positive anti-HBc IgM Ab (0.303/0.221) (DiaSorin, Italy).

Example 1: Extraction and Amplification of HBs DNA

5 DNA was isolated and purified from 40 uL samples based on a guanidinium-thiocynate (GuSCN) lysis method. The single-step method of RNA isolation by acid guanidinium thiocyanate-phenol-chloroform extraction was used with some modifications. Five volumes of lysis solution [5.75 M GuSCN, 50 mM Tris-Cl pH7.5, 100mM 2-mercaptoethanol and 15 ug/mL poly (A)] were added to 1 volume of serum. 10 After a brief vortex, the mixture was heated at 60°C for 10 minutes. The DNA pellet was obtained with isopropanol precipitation, and was washed with 75% ethanol. 15 Dried DNA pellet was then resuspended in 50 uL of PCR reaction solution, with 40 uM (each) of the first-round primers (F1-6 and R1-6). The mixture was heated to 95°C for 3 min, followed by 30 PCR cycles consisting of 94°C/45 sec, 55°C/45 sec and 72°C/45 sec in a thermal cycler (GeneAmp PCR System 9600, Perkin Elmer, 20 USA). 0.5 uL of the first-round PCR product was then served as template for a second-round PCR amplification using F1-7 and R13-2d primers pair consisting same cycles except annealing temperature was raised to 60°C. 25 Positive PCR products, a DNA band of 604bp as expected, were detected in agarose gel electrophoresis.

The PCR Primer sequences [nucleotide sequences were derived from HBV DNA (accession number J02203) were as follows:

First-round Primer Set:

5 F1-6 (231-252): CCTCACAATACCGCAGAGTCTA  
R1-6 (816-842): AGGGTTTAAATGTATACCCAAAGACAA

Second-round Primer Set:

F1-7 (246-268): GAGTCTAGACTCGTGGTGGACTT  
R13-2d (822-843): ccgaattcTAGGGTTTAAATGTATACCCA

10 An EcoR I site was added at the 5'-end of R13-2d for cloning purpose.

Example 2: Sequence Alignment and Phylogenetic Analysis

15 Amplified PCR product was cleaned with a QIAquick spin column (Qiagen) and subsequently cloned for DNA sequencing and protein expression. Five clones were sent for DNA sequencing in order to obtain reliable DNA sequence determination. Nucleotide sequences were determined for both strands with the BigDye Terminator  
20 Ready Reaction Kit (PE Applied Biosystems, USA) on an ABI 377 DNA Sequencer (PE Applied Biosystems, USA). Sequence analysis was performed using SeqMan 4.00 module of the Lasergene package (DNASTar Inc., Madison, WI, USA). Sequence alignment and the construction of  
25 phylogenetic trees were computed by MegAlign 4.00 module of the Lasergene package (DNASTar Inc., Madison, WI, USA). Clustal multiple sequence alignment was used through sequence weighting. The 28 reference strains for genotype grouping were derived from published sequences.

### Example 3: S-HBsAg Cloning and Transient Protein Expression

The PCR product was digested by Xba I /EcoR I restriction enzymes. The 595 bp fragment encoded 86% of the S-HBsAg protein from amino acids Leu 32 to the end (Ileu 226). The fragment was then ligated into a previously constructed mammalian expression vector, to replace the wild-type ayw S-HBsAg fragment, which was placed downstream of a CMV promoter. The transfection was then performed on a COS-7 cell line using LIPOFECTAMINE Plus reagent (Life technologies, MD, USA). Culture supernatant containing secreted variant S-HBsAg from the COS-7 cell infections was then harvested and fresh medium was added every 72 hours after transfection. Wild-type ayw [wt(ayw)] S-HBsAg, (GeneBank accession number J02203), was also expressed for control use.

### Example 4: Recombinant HBsAg Antigen Immunoassay and Epitope Analysis

Recombinant wt(ayw) and LBN variant S-HBsAg expression was determined by solid-phase EIA in a sandwich format. One polyclonal and a panel of six monoclonal antibodies [mAb(s)] were used in this study. They were goat anti-HBsAg (ay/ad) (Fitzgerald, MA, USA), HB-1, HB-8, HB-9, HB-13, HB-14 and HB-16. All six mAb(s) were raised against serum derived wild-type HBsAg and were reactive to both ad and ay subtypes. EIA were used to measure serum and recombinant HBsAg reactivity. Basically, purified mAb(s) or polyclonal anti-HBsAg were coated on

a microtiter plate and kept at 4°C until use. Prior to performing EIA, the plates were blocked with PBS containing BSA for 2 hours at 25°C. EIA was performed in a one-step sandwich format with 150 uL of sample (serum or diluted recombinant HBsAg culture) mixed with 50 uL HRP conjugated monoclonal antibodies. The plates were incubated at 37°C for 90 minutes, then washed 6 times with PBS containing 0.005% Tween 20. The plates were developed by a final incubation for 30 minutes with 200 ul of OPD solution (Sigma, USA). Adding 50 uL of 4N Sulfuric acid then stopped the color development. The absorbance was read on an automatic microtiter plate reader (Molecular Devices, USA) and the results were expressed as optical density (OD) units at 490 nm. To evaluate the mAb reactivity to the native HBsAg and to the synthetic peptides, direct EIA procedure was performed. A serial dilution of each purified and quantity adjusted mAb was incubated on plates, which were previously coated with purified native HBsAg or oxidized peptides. Bound murine IgG were detected by a second incubation with horseradish peroxidase conjugated rabbit anti-mouse IgG. The reactivity was ascertained by enzyme catalyzed OPD color development. Recombinant variant and wild-type S-HBsAg were also analyzed by western immunoblot. HBsAg culture supernatant was concentrated 15 fold by a centrifugal filter (Biomax-100, Millipore, USA). The concentrate was run on a NuPAGE 10% Bis-Tris SDS Gel (Novex, San Diego, USA) and

region (Stirk HJ, Thornton JM, Howard CR. A topological model for hepatitis B surface antigen. Intervirology. 1992;33(3):148-58)

5     Example 6: Recombinant HBsAg Transient Expression in COS-7 Cell

10     The secreted recombinant HBsAg expression was in a range of 0.1-0.2 mg/liter, calibrated by a purified wild-type recombinant HBsAg. Only secreted HBsAg in culture supernatant was examined for expression. There was no significant expression yield difference at 72 hours and 144 hours time point. The culture supernatant harvested at 216 hours gave only 1/5 expressed HBsAg compared to the supernatants collected at 72 and 144 hours.

15     Example 7: Immunoreactivity Analysis:

20     Both the recombinant HBsAg (ayw) and the novel variant HBsAg (LBN) culture supernatants were tested for their reactivity by a panel consisting of six mAb(s). Culture supernatants were diluted 1:40 to insure the same quantity of antigen concentration. Amino acid mutations apparently affected four mAb(s) binding affinity to wt HBsAg. HB-16 was affected most, losing almost 90% strength. Strikingly, the binding strength of two mAb(s), HB-13 and HB-14, to the LBN variant was  
25     significantly increased to 5-6 fold. Peptide mapping revealed that these two antibodies were specific to the first loop linear sequence while mAb HB-9 was specific to the sequence from 137 to 147, located in the second

loop region. All the three mAb(s), HB-1, HB-8 and HB-16,  
are conformation specific. They did not react with SDS  
denatured HBsAg in immunoblot but had higher dilution  
titer in direct EIA assay. On the other hand, the mAb(s)  
5 HB-13 and HB-14 blotted to both wild type and LBN HBsAg  
very well, indicating that these two mAb(s) recognize  
denatured epitopes, independent of the mutation sites.

Table 1. Immunol reactivity of a panel of monoclonal antibodies to various antigens in EIA assay and in western immunoblot

\* Relative reactivity was presented as OD derived from each mAb reactivity to LBN variant compared with OD derived from its reactivity to wt(ayw) which was set at 100%.

\*\* mAb titer was expressed as dilution needed for each mAb to obtain a preset signal between OD=1.00 to 1.25 in a direct EIA with native HBsAg.

# Reactivity was expressed as OD obtained from each mAb at indicated dilution. All mAb(s) concentration was adjusted at a same concentration start point. All peptide sequence was based on wt(ayw).

n.p. : not performed. Western immunoblot results were visually determined.
